**KNOWLEDGE EXCHANGE IN ELECTRONIC NETWORKS OF PRACTICE;
TOWARDS A CONCEPTUAL FRAMEWORK**

Eoin Whelan¹

¹ Centre for Innovation & Structural Change, National University of Ireland, Galway, Ireland. Eoin.whelan@nuigalway.ie

Abstract

The recently developed knowledge-based view of the firm argues that knowledge is the firm's most valuable resource. Within this field of study, informal social networks are rapidly gaining attention as mechanisms which facilitate knowledge flows. Electronic networks of practice are a special case of informal networks where the sharing of practice related knowledge occurs primarily through computer-based communication technologies. However, we know relatively little about the dynamics of knowledge exchange which occur in these electronic networks. This paper posits that there is a relationship between the structural properties of electronic networks of practice and successful knowledge exchange. The theoretical positions of social network theory and the knowledge-based view of the firm are used to support this claim.

KEYWORDS

Knowledge, networks of practice, electronic community, social networks

1. INTRODUCTION

Over the past two decades, as a result of managerial initiatives such as delayering, reengineering and team-based designs, most organisations have become flatter and more flexible. This has significantly changed the way work gets done. Employees are no longer constrained by the role of formally prescribed relationships in organisations. More work is being done through informal networks and "*supporting collaboration and work in these informal networks is increasingly important for organisations competing on knowledge and an ability to innovate and adapt*" (Cross et al. 2002). Informal relationships among employees are often far more reflective of the way work happens in an organisation than the relationships established by position within the formal structure (Cross et al. 2002). Yet, these relationships rarely appear on formal organisational charts.

Further pressure is being placed on organisations by the increased internationalisation of business resulting in collaboration and cooperation becoming more distributed. Collaboration between organisations has come into focus in recent years with the recognition that success in a global economy comes from innovation. This is the only way an organisation can keep pace with the rapid developments in technology, increasingly demanding customers and changes in the competitive environment through deregulation, social changes, and the actions of competitors. Innovation depends on the exchange of ideas and insights through trusted relationships, which depend on knowing how to collaborate effectively (Nooteboom 2004).

The diffusion of innovative knowledge has become one of the major research interests in management. Traditional organisational forms (markets and hierarchies) show serious deficits in organising the complex nature of knowledge (Jones et al. 1997). This has led to an increased interest in the community of practice (CoP) concept. A CoP consists of a relatively tight knit group of members who know each other, work together face-to-face, and continually negotiate, communicate, and coordinate with each other directly. CoPs are regarded as the essential building blocks of the knowledge economy and are being promoted within organisations as sources of competitive advantage (Teigland et al. 2004). Current research has focused on the role of CoPs for encouraging knowledge exchange and innovation *within* organisations; however, we know much less about the role that members of CoP play in creating linkages to external knowledge sources. Previous research has found that organisational members may simultaneously be members of a CoP as well as members of broader occupational communities (Van Maanen et al. 1984). These individuals perform the dual roles of generating local knowledge within an organisational CoP while providing linkages to knowledge and innovations outside of the organisation. These inter-organisational networks have been referred to as networks of practice (NoPs). NoPs are social structures linking similar individuals across organisations who are engaged in a shared practice but who do not necessarily know one another (Brown et al. 2000).

While the participation of individuals in NoPs is not a new phenomenon, the ability to access these networks has increased due to recent advances in information and communication technologies. Electronic networks of practice (ENoPs) are a special case of NoP where the sharing of practice related knowledge occurs primarily through

computer-based communication technologies (Wasko et al. 2005). In ENoPs, individuals may never get to know one another or meet face-to-face. They generally coordinate through technologies such as blogs, listservs, or bulletin boards. Previous research has shown that external knowledge trading through ENoPs is beneficial for the firm (Bouty 2000; Teigland et al. 2003), thus making the study of ENoPs of prime interest for researchers and practitioners.

This paper examines ENoPs through the theoretical lens of social network theory. This body of literature shows that particular structural properties of networks create or constrain possibilities for action by individuals and networks. The overarching goal of this research-in-progress is to improve our understanding of electronic networks from a business firm's perspective, and in particular to investigate issues of structure and performance, two important areas generally left by the wayside in previous NoP research. This paper posits that there is a relationship between the structural properties of ENoPs and successful knowledge exchange. To support this claim, a review of the knowledge-based view of the firm is presented in section 2. A conceptual framework which links the roles of CoPs to ENoPs within the knowledge-based view of the firm is presented in section 3. Section 4 gives a brief overview social network theory. Given the size constraints of this paper, we have chosen to focus on one particular structural property i.e. core/periphery structure. The relationship between the core/periphery structure of a network and performance is explored further in this section. Finally, the mechanisms to be used to examine ENoP structure and knowledge exchange are detailed in section 5.

2. KNOWLEDGE-BASED VIEW OF THE FIRM

This study is grounded in the knowledge-based view of the firm. This recently developed theory argues that knowledge is the firm's most valuable resource. Producing unique products and services or producing them at a lower cost than competitors is based on superior knowledge of the production process and superior design. In fact, prominent authors such as Drucker (1994), Grant (1996, 2001) and Spender (2003) suggest that knowledge is perhaps the only true source of competitive advantage.

Much tension exists as to the different views of knowledge. This debate is essentially centred on whether knowledge can be captured, stored and transferred. Many people feel that if something is to be managed, it must be able to be quantified, counted, organised and measured (Glazer 1998), and it must be able to be built, owned, controlled and its value maximised (Davenport 1997). This view of 'management' has influenced attempts to manage knowledge by quantifying, capturing and controlling it as an object. The emerging field of knowledge management (KM) has also attracted some criticism because of this, much of which relates to the perceived over-emphasis on codifying and storing knowledge as data. There is a real danger that KM is just becoming another label for information systems rather than an innovative attempt to increase knowledge in the organisation (Goldkuhl et al. 2002). More recent developments have recognised that this approach to the KM is too restrictive and that some aspects of knowledge cannot be captured. This debate has led to a confused picture of knowledge within the KM community as researchers and practitioners have sought to define the knowledge which can be captured and that which cannot. For example, some commentators are of the

opinion that tacit knowledge can be captured (Huang 1997), some feel it is merely 'difficult' to articulate (Teece 1998), others feel it cannot be codified without being invalidated (Buckingham Shum 1997) whereas others feel it simply cannot be captured or codified at all (Leonard et al. 1998).

There is a clear need for a different view of knowledge in order to overcome this challenge of managing knowledge which cannot be captured, codified and stored. In regards to this, Hildreth et al. (2002) argue that knowledge is not made up of mutually exclusive opposites of hard and soft (see figure 1). Instead, they are mutually dependent where all knowledge is regarded as being both hard and soft. Only the proportions differ. Viewing knowledge in this way lends itself more easily to the notion that knowledge can be exchanged through digital media. It is recognised that higher levels of tacit knowledge can be exchanged through face-to-face contact. However, knowledge can be made more transportable by increasing the hard/explicit element in relation to the soft/tacit element.

Figure 1 - Knowledge consists simultaneously of both "Hard" and "Soft" Knowledge (Hildreth et al. 2002)

Assuming that knowledge is a critical input to production processes, then competitive advantage stems from the ability to integrate the specialised knowledge of individuals (Grant 1996; Nonaka 1994; Spender 2003). Therefore, one of the key issues underlying the knowledge-based view of the firm is to understand how knowledge is integrated into the firm to create competitive advantage (Hansen 1996). Informal networks such as NoPs, are rapidly gaining attention within this view of the firm. Knowledge may be the organisations most valuable resource however, no firm can possess all the knowledge it requires. Therefore it must look outside its formal boundaries (Wasko et al. 2005). Nooteboom (2004) suggests that in dynamic fields, organisational innovations derive

from knowledge exchange and learning from network connections that cross organisational boundaries. Organisation members benefit through informal interaction by acquiring knowledge they did not have.

3. CONCEPTUAL FRAMEWORK

When individuals have a common practice, knowledge readily flows across that practice, enabling individuals to create social networks to support knowledge exchange (Brown et al. 2000). In fact, Brown et al. (2000) conclude that the key to competitive advantage is a firm's ability to coordinate autonomous CoPs internally and leverage the knowledge that flows into these communities from network connections.

Findings from a recent study by Teigland et al. (2004) suggests that knowledge in a tightly knit CoP may be largely redundant, providing little additional information over what an individual may already know, thus impeding the ability to develop new and creative ideas. The highly efficient structures which support knowledge integration in a CoP may evolve into core rigidities and competency traps – inappropriate knowledge sets that preserve the status quo and limit new insights (Leonard et al. 1998). One way to alleviate this concern is to use ENoPs to create 'bridging links' between strong tie communities to enhance the flow of new ideas and knowledge. Electronic networks have certain advantages over social networks, mainly in rapidly transferring explicit knowledge, rapidly developing weak ties and greatly reducing communication costs (Grandori et al. 1995).

A conceptual framework which connects the above views together is presented in figure 2. Internal to each organisation are a number of CoPs. Through conversation, mentoring, war stories etc, CoP members help each other to make sense of ambiguous, problem-centred situations. Due to the increased access of information and communication technologies, members of internal CoPs may also be members of external ENoPs. These individuals are able to acquire new knowledge from these external sources and integrate it into their internal CoPs. Through this process they are able to build competitive advantage by combining new and existing knowledge to generate novel ideas and solve complex problems.

A key question for researchers and practitioners is how to turn an empty electronic space into a vital, active forum devoted to knowledge exchange (Teigland et al. 2004). This research contributes to this inquiry by focusing specifically on the structural properties of ENoPs and their relationship with successful knowledge exchange. Structural property concepts are reviewed in the following section.

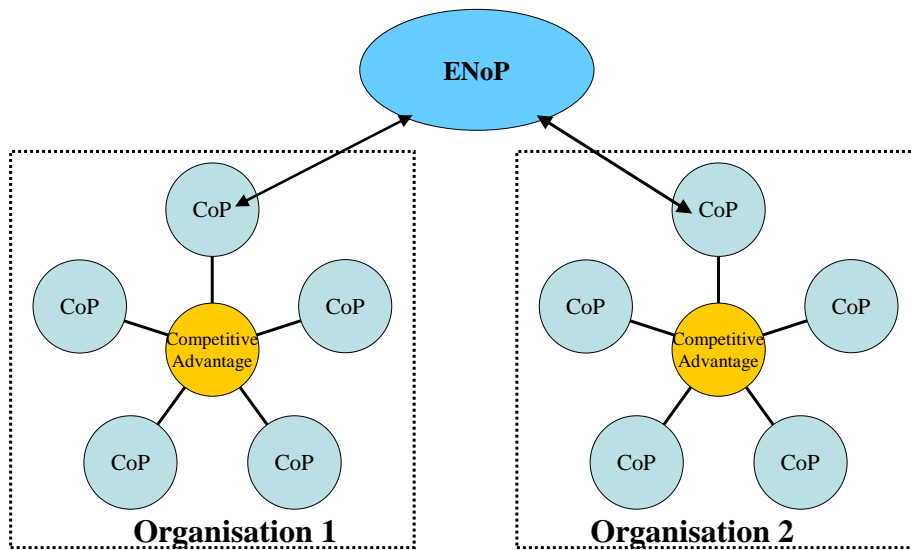

Figure 2 – The Conceptual Framework

4. SOCIAL NETWORK THEORY

In the field of social psychology, an important tradition of study on networks, is that of social network theory. Social network theory views social relationships in terms of nodes and ties. Nodes are the individual actors within the networks, and ties are the relationships between the actors. It indicates the ways in which they are connected through various social familiarities ranging from casual acquaintance to close familial bonds. In its most simple form, a social network is a map of all of the relevant ties between the nodes being studied (see figure 3).

The power of social network theory stems from its difference from traditional sociological studies, which assume that it is the attributes of individual actors that matter. Social network theory produces an alternate view, where the attributes of individuals are less important than their relationships and ties with other actors within the network. It suggests that at least some properties and outcomes of a social network are a function of its complete structure and are not reducible to either an individual actor or a single link (Dejenne et al. 1999).

Figure 3 – Social Network Map

The structural properties of the social network help determine the networks usefulness to its individuals. When talking about the structural properties, what is meant is the impact of group communication structure on collective performance outcomes. Structural properties refer to concepts such as density, connectedness, centrality, core/periphery structure, coreness etc. For the purpose of this paper, one structural property is selected i.e. core/periphery structure, and its relationship with network performance is examined.

A network has a core/periphery structure if it can be partitioned into two sets: a core whose members are densely tied to each other, and a periphery whose members have more ties to core members than each other (Borgatti et al. 1999). Research into core/periphery structure has a long tradition dating back to 1940s and 1950s. This body of literature consistently shows that networks with a strong core/periphery structure are better for the diffusion of routine information, while networks with weak core/periphery structure are better for solving complex tasks (see figure 3 and 4). For example, Bavelas (1948) showed that 'communication nets' with centralised structures (e.g. wheel) improved the diffusion of information in simple tasks while decentralised structures (e.g. circle) delayed the diffusion of information. Groups with decentralised communication nets took less time to finish complex tasks than groups with centralised structure (Shaw 1964). More recently, Cummings et al. (2003) found that strong core/periphery structure was negatively related to group performance for complex, non-routine work.

Figure 3 – Weak Core/Periphery Structure

Figure 4 – Strong Core/Periphery Structure

It has only been in recent years that network analysis has captured the attention of the business world on a broad scale. Yet despite the increase in the use of work groups in organisations, there has been relatively little social network research on the structural properties of natural work groups and the consequences for performance (Cummings et al. 2003; Schenkel et al. 2001). Social network scholars have tended to focus on structural properties of ego-centric networks or bounded networks within an organisation. Cummings et al. (2003) also suggest that field work is needed to revisit which structures have meaningful consequences for performance.

5. METHODOLOGY

ENoP research is still in its infancy and we know little about the dynamics of knowledge exchange in these significant organisational forms. Previous research has been limited by the fact that researchers have tended to concentrate on only one ENoP, usually internal to one organisation (Teigland et al. 2003; Teigland et al. 2004; Wasko et al. 2005). Empirical evidence which links ENoP structures to performance is needed as previous research in the social network field shows that informal methods of knowledge transfer are more effective than formal processes (Burt 1992; Grant 1996). As a step in this direction, this research will address the following question; *what is the relationship between ENoP structural properties and successful knowledge exchange for complex, non-routine work?* A set of hypotheses which relate the two variables (i.e. ENoP structural properties and successful knowledge exchange) will be developed and tested. Previous research will be extended by analysing multiple categories of knowledge workers across multiple organisations.

The first stage of this research will be to identify six to eight inter-organisational ENoPs. For example, one might be an open-source software network; another might be a discussion forum for chemical engineers etc. Once identified, the structural properties of the ENoPs will be measured using a tool called social network analysis. This tool provides both a graphical display of the network as well as precise mathematical measures of its structure (i.e. density, connectedness, centrality, core/periphery structure, coreness etc). The second stage will involve measuring the success of the knowledge exchanged through these electronic networks. Successful knowledge exchange in ENoPs is determined by both the quantity of knowledge exchanged as well as the quality. Knowledge quantity will be measured by a process called content analysis. To measure the quality of knowledge exchanged in an ENoP, an expert from each field will rate the usefulness of responses posted. A survey of ENoP participants will serve as a second measure of knowledge quality. For example, participants can be asked how useful they found the ENoP for solving complex problems. To test the hypotheses, the various measures of ENoP structural properties will be related to the measures for successful knowledge exchange.

6. CONCLUSION

This paper posits that there is a relationship between the structural properties of ENoPs and successful knowledge exchange. The knowledge-based view of the firm and social network theory are used to justify this claim. The knowledge based view of the firm argues that knowledge is the firm's most important strategic asset while social network theory shows that network outcomes are determined by its structure. A conceptual framework which links a firm's competitive advantage to the interaction of face-to-face CoPs and inter-organisational ENoPs has been presented. Further research will involve developing hypotheses which relate ENoP structures to successful knowledge exchange. These hypotheses will be applied to multiple categories of ENoPs and tested.
